The aim of the present study was to report our experience in performing aortic arch repair in redo-surgery. A total of 962 patients underwent surgery at our institution during the period 1995-2005. Data from all the procedures performed on this subset of patients were reviewed. From this group, 64 patients underwent aortic arch repair. Forty-two patients were reoperated due to aortic arch aneurysms, while the remaining 22 patients were redo-surgery due to different types of arch pathology. Three groups were identified based on the type of aortic pathology: i. arch aneurysm and complete arch replacement (Group 1); ii. arch aneurysm and replacement of the ascending and arch aorta (Group 2); iii. Type A aortic dissection and replacement of the ascending and arch aorta (Group 3). Overall hospital mortality was 14.4%, with a better outcome in Group 3. An additional 4.8% of patients presented with major perioperative complications in the early postoperative period. Multivariate analysis showed that the independent predictors of hospital mortality were: the necessity of a mechanical or partial circulatory arrest and a long interval between the previous aortic surgery and the redo-surgery. In-hospital mortality in redo-surgery for aortic arch pathology is more than double the mortality of an initial procedure, in part due to an increase in the need for more complex procedures. Nonetheless, hospital survival remains fair, even in redo-surgery for complex diseases. Any discussion of the background art throughout the specification should in no way be considered as an admission that such art is widely known 2492ce491b
