Mesenchymal stem cells (MSCs) were first isolated in 1957. As a result of their close relationship with bone, they were characterized as multipotent cells capable of differentiating into bone cells (osteogenic), cartilage (chondrogenic), adipose tissue (adipogenic) and muscle (myogenic). Their relevance was demonstrated in bone defects

of increasing severity, and their use was expanded in other tissue defects and in a growing number of pathologies. Over the years, the growing interest for clinical translation of MSCs has increased the knowledge and understanding of the regulatory pathways of the MSCs and their capacity to differentiate into cells of several lineages, such as endothelial, cardiomyocyte and smooth muscle cell, thus allowing for more specific cell therapies. In recent years, and following the technical advances that have been achieved in basic research, MSCs have been used in a variety of clinical applications. Here, we review the relevance of the MSCs and their clinical use with a focus on their use in clinical practice and their current challenges. We discuss the basic science knowledge regarding MSCs that has contributed to the expanding use of these cells for several clinical applications, their use in disease and the challenges that are involved in translating basic science into clinical practice.Q: strtok behaviour on NULL string How is the behaviour of strtok on NULL string. This is the sample code I am using. char *p1, *p2; strtok(NULL, " \t "); p1 = strtok(NULL, " \t "); p2 = strtok(NULL, " \t "); How can I print the p1 and p2? A: From the strtok manpage: Return Value The function returns the next token found after the initial delimiter, or a null pointer if the end of input is reached before any token was found. So, in your example, the p1 and p2 pointers will both be pointing at the beginning of a (blank) string. To get around this, pass a 2d92ce491b
